## Reservoirs in the Altiplano

- In the Bolivian Altiplano are placed two big lakes and two dry lakes (*salares*). In short and long time they are very sensible to climate.
- Titicaca lake has 8000 km<sup>2</sup>, Poopo lake has 3000 km<sup>2</sup>. The first one is deep and the second very shallow, with average deep only of 1.5 m.
- The Poopo lake according to the last modern climate period should be considered as terminal lake and very dependent.

# “PROYECTO GRANDE”

## Reservoirs in the Altiplano

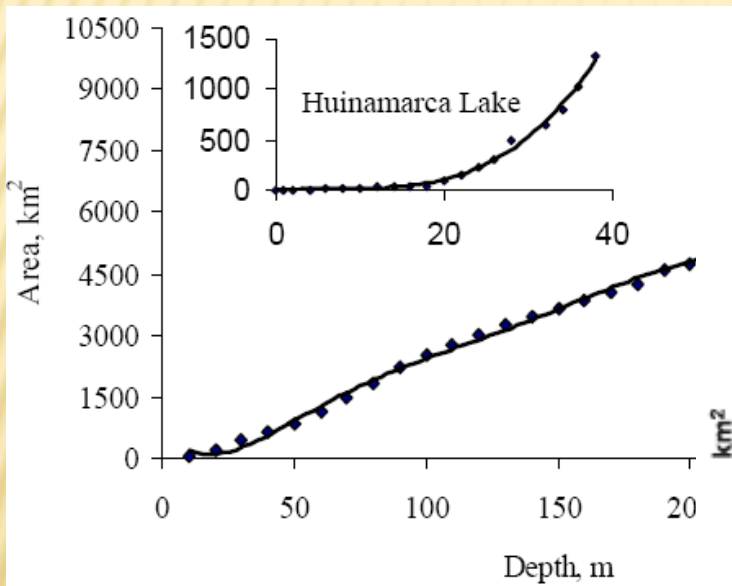

- Successive limnological studies have been carried out in the Titicaca lake and has been identified different lake paleo-levels.
- The water levels oscillation at least for the last 170 000 years has been registered by several researchers . One thousand years ago Titicaca was divided in two lakes.
- Thus the Titicaca lake studies were prioritized not only the hydrological issue.

# “PROYECTO GRANDE”

## Reservoirs in the Altiplano

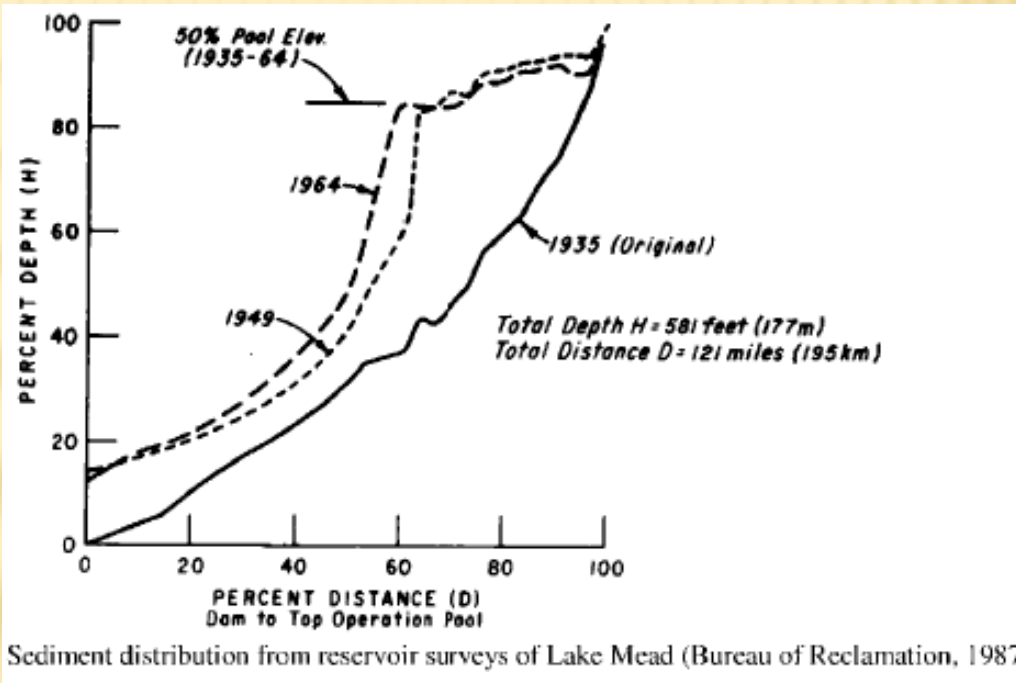

- The modern hypsographic curve of the Altiplano lakes (Titicaca and Poopo)

# “PROYECTO GRANDE”

## Reservoirs in the Altiplano

- Typical morphological changes of the reservoirs (Lake Mead, USA)

# “PROYECTO GRANDE”

## Sedimentation processes of shallow Poopo

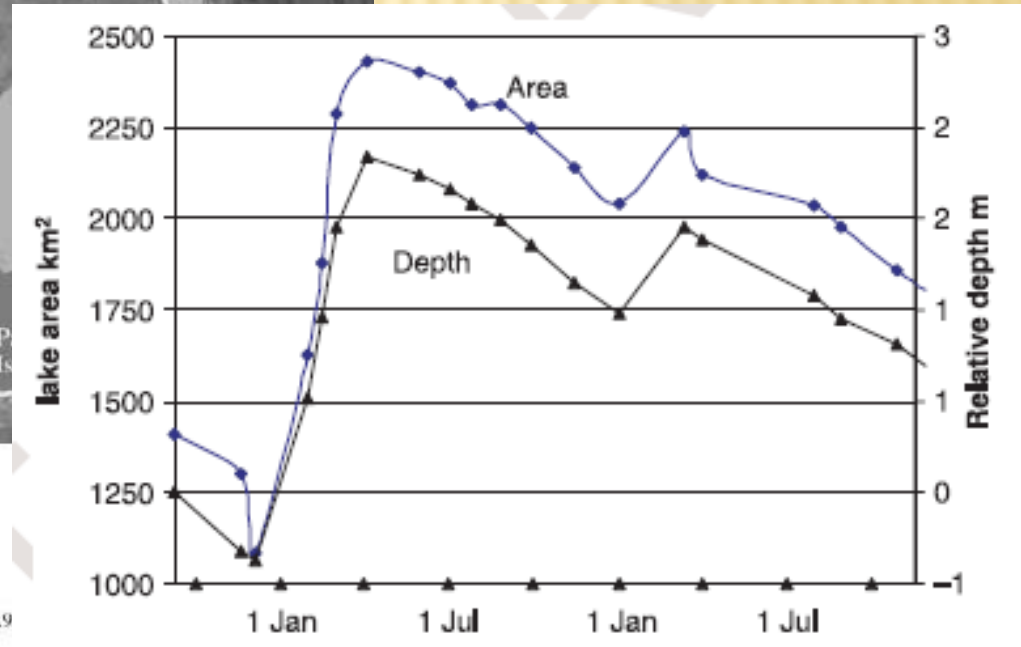

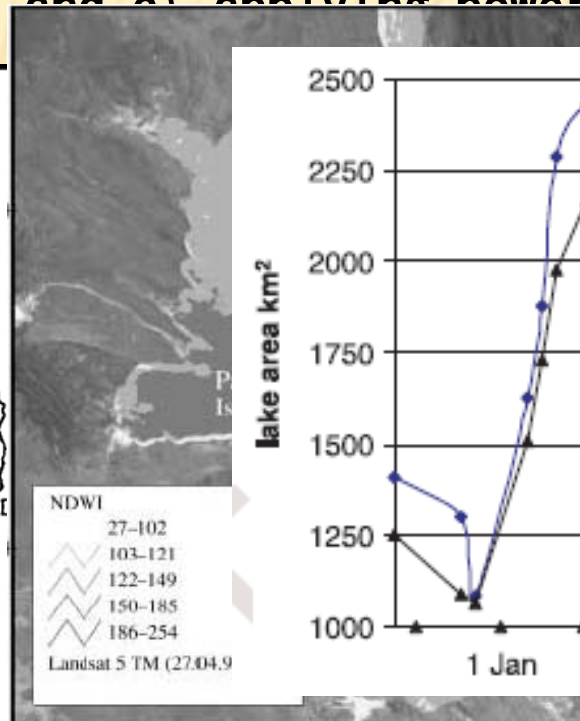

- The water level oscillation is extreme with surface area changing from 2500 to 1000 km<sup>2</sup>. If water depth is less than 1 m at the end of the rainy season, the lake disappears.
- The shores are very shallow and wind force easily could move up the shores hundred of meters.

# “PROYECTO GRANDE”

## Sedimentation processes of shallow Poopo lake

- There was defined and analyzed first the hypsographic curve of the lake trough different methods: a) Bathymetry consisting in lake leveling , measuring single deep point and analyzing satellite images and computing water index, b) computing water balance for the lake and c) applying power equation.

# “PROYECTO GRANDE”

## Sedimentation processes of shallow Poopo Lake

$$A = A_{\text{base}} + A_0 (h/h_0)^{2/P}$$

- Thin line come from lake leveling and satellite image analysis; the isolated squares corresponds to water balance computation; and the thick line to power equation.

## “PROYECTO GRANDE”

# Sedimentation processes of shallow Poopo lake

- The hypsographic curve of the Poopo lake could change due to of re-suspension within the lake, and sediment transport from the 24 regional rivers and one big river.
- The annual sediment transport in the Desaguadero big river during 1992–1993 was estimated at  $6 \cdot 10^6$  tn/year, which corresponds to a sedimentation rate of the lake of 2 mm/year, or 4 cm in 20 years.
- The concentration of suspended solids was found to be changes from 250–180 mg/L.
- Redistribution on the bottom sediments could change the bathymetry of the shallow lake.

## “PROYECTO GRANDE”

# Sedimentation processes of shallow Poopo lake

- There is more sediment to settle in a deep water than in shallow one, but waves erode bottom material more in very shallow water and the deeper parts would tend to become more shallower also.
- The resuspension and resettling can take over the whole lake bottom of Poopo lake.
- Since there is no banks around the lake, the water processes probable change the morphology very slowly, but there is no information to verify this conclusion.
- Is more likely that morphological changes could occur because of single events, rather than continuously over time, such as the wind event, which moves the water hundred of meters up the shores.

Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

# “PROYECTO GRANDE”

## Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

- Whole Tuni basin area = 195 km<sup>2</sup>.
- Tuni glacier watershed surface area = 25 km<sup>2</sup>
- Tuni water surface area = 2 km<sup>2</sup>
- Maximum water depth = 30 m
- Average water depth = 15 m

## “PROYECTO GRANDE”

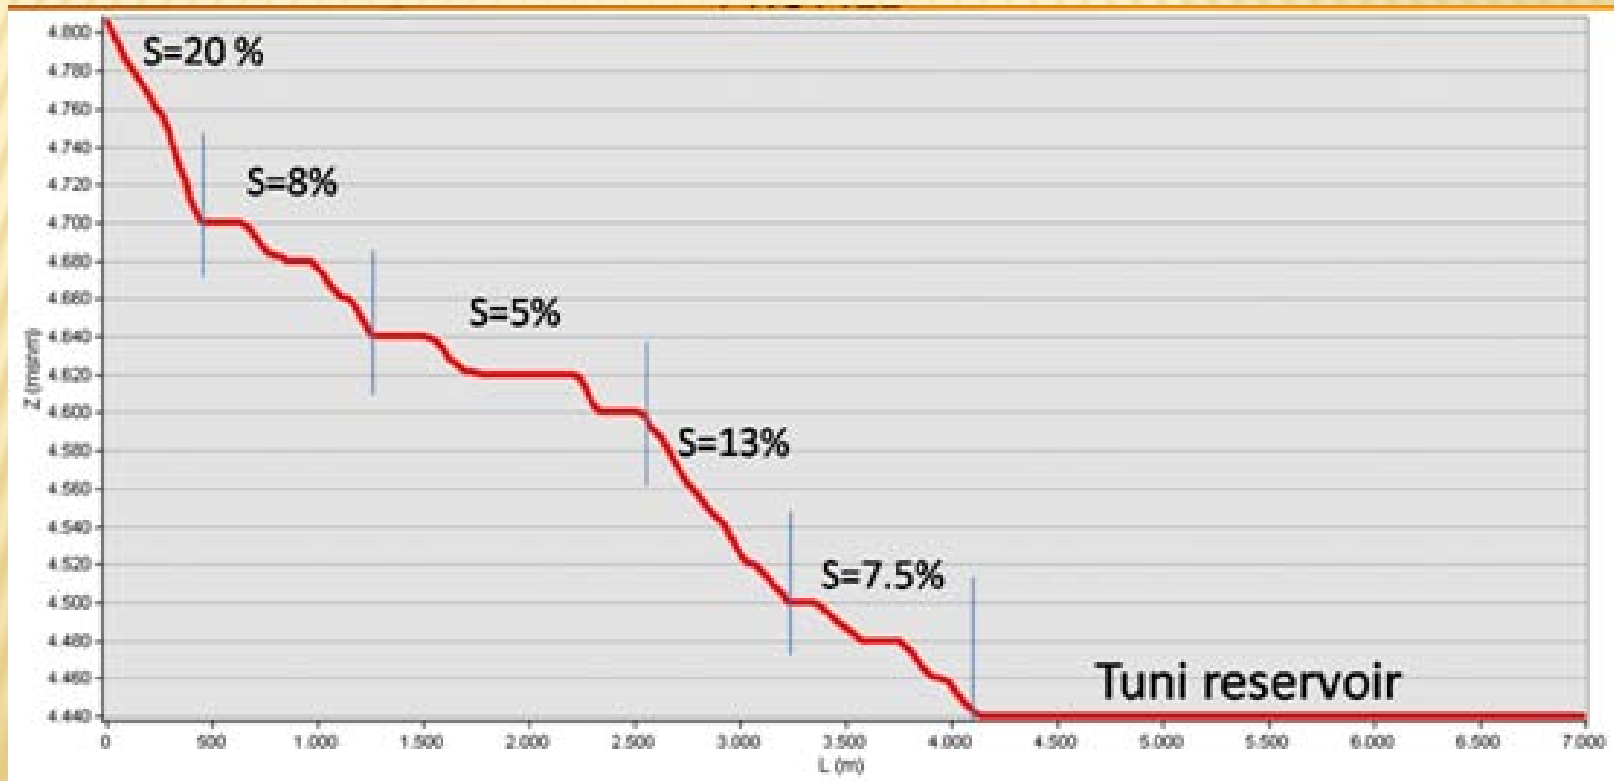

Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary

Parameters	Value
Area of the basin (Km <sup>2</sup> )	195.7
Perimeter of the basin(Km)	77.9
Compactness ratio	1.57
Average elevation (msnm)	4947
Drenaje density (Km/km <sup>2</sup> )	1.13

# “PROYECTO GRANDE”

## Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

Tuni reservoir glacier watershed profile

# “PROYECTO GRANDE”

## Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

- Hypsographic curve of whole Tuni River basin

# “PROYECTO GRANDE”

## Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

• Hypsographic curve of Tuni glacier watershed

# “PROYECTO GRANDE”

## Sediment transport pattern and sedimentation in Tuni glacier reservoir, preliminary interpretations

- To raise the issue and hypothesis of research are the followings:
- The generation of erosion and sediment transportation data.
- Production and sedimentation models.
- Sedimentation model under climate changes of the reservoirs.

Also could be then:

- The sediment trap along Tuni river and regulation capacity of the watershed
- Analysis of the practices for sediment transport control
- Re-suspension of the sediment in the Tuni glacier basin
- Morphological changes prediction of the Tuni reservoir
